

# Two Mechanistic Pathways for Substitution

One step mechanism:  $[S_N2] = [A_N] + [D_N]$

This symbol means bimolecular nucleophilic substitution

$[S_N2]$  involves  $\sigma$ -bond making & breaking

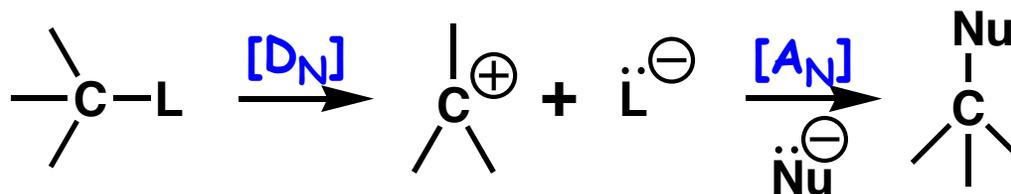

An  $n \rightarrow \sigma^*$   $\sigma$ -type interaction

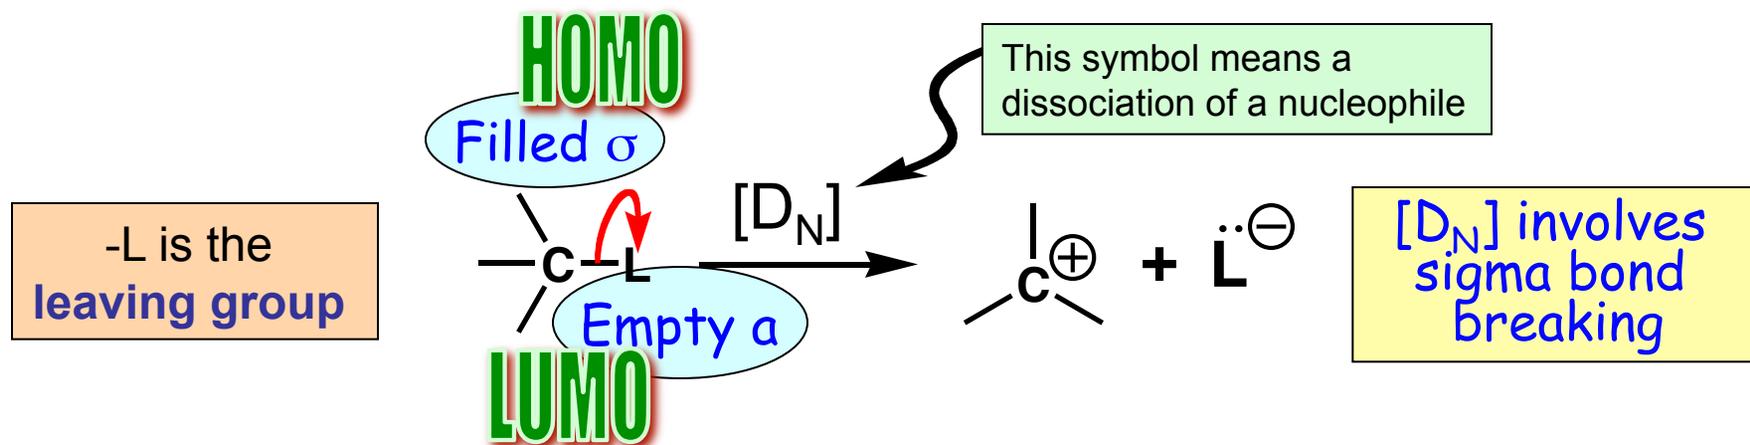

Here bond making and breaking take place at the same time - a **concerted** process. Any one-step process is its own elementary step. So we'll call the elementary step that results from **concerted** combination of  $[A_N] + [D_N]$  the  $[S_N2]$  step, which stands for **nucleophilic, bimolecular substitution**. It's bimolecular because two species must come together. We need to re-consider the frontier orbitals involved in this new elementary step. The tail of the first arrow implies the filled orbital (HOMO) is a non-bonded electron pair,  $n$ . The head of the first arrow points to the empty orbital (LUMO,  $\sigma^*$ ) that accepts the electron pair. The empty orbital may not be obvious until you realize that the C-L sigma bond breaks, as implied by the tail of the second arrow. Sigma bond breaking would result upon filling  $\sigma^*$  with the electron pair from  $n$ . The frontier orbitals align coaxially (a  $\sigma$ -type interaction).

Two step mechanism:  $[S_N1] = [D_N]$  then  $[A_N]$

The second pathway is a **sequential** combination of  $[D_N]$  followed by  $[A_N]$ . This **sequential, two-step** mechanistic pathway is called **unimolecular nucleophilic substitution**, or  $[S_N1]$ . The slowest step is the unimolecular  $[D_N]$  process, hence the "unimolecular" in the name. The most important thing to realize is that the  $[S_N1]$  pathway will only be available if a stable carbocation can form.

# Substitution Mechanisms Require New Elementary Steps: Nucleophile Dissociation $[D_N]$ & the Nature of Leaving Groups

**$[D_N]$  involves a  $\sigma \rightarrow a$  “no-bond” interaction**

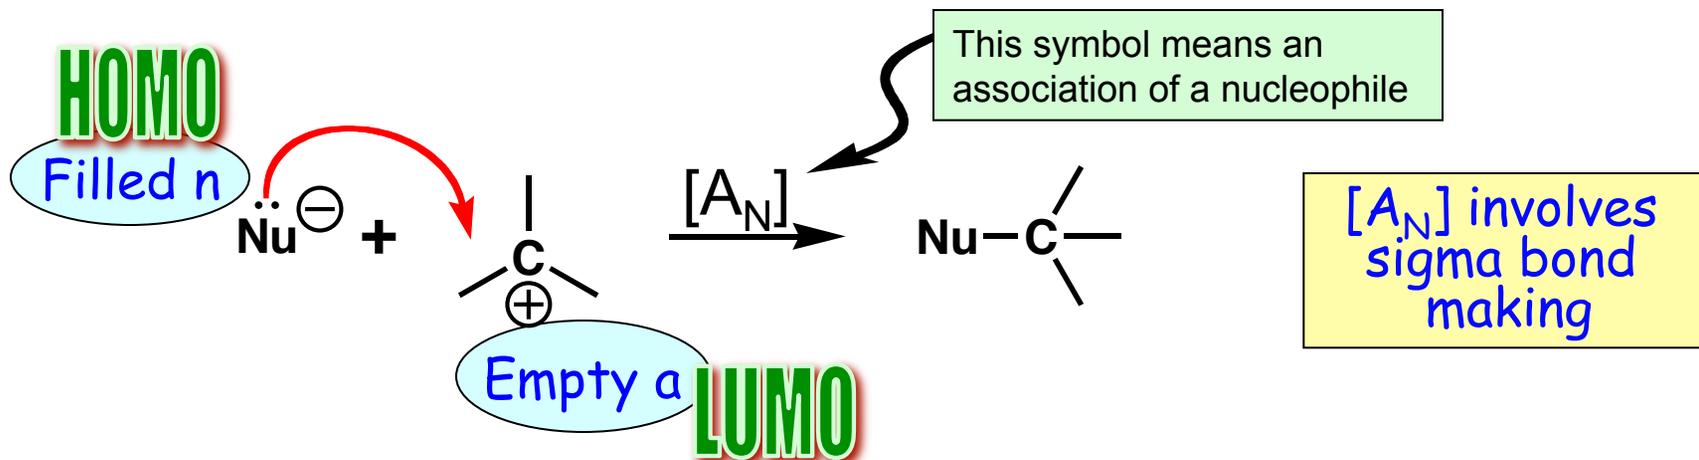

## Curved Arrows Imply the Frontier Orbitals

Curved arrows indicate the HOMO-LUMO pair (Frontier Orbitals) involved in an elementary step. The tail of the arrow implies the filled orbital (HOMO) is  $\sigma$  electron pair. The head of the arrow points to an atom on the leaving group (L) suggesting that an atom-centered empty orbital (LUMO,  $a$ ) accepts the electron pair. The process produces no new bonding interactions. **A good leaving group will have a high energy  $\sigma$  and low lying  $a$ .**

	empty	$\sigma^*$	$a$	$\pi^*$
filled		$\sigma^*$	$a$	$\pi^*$
$\sigma$		$\sigma \rightarrow \sigma^*$	$\sigma \rightarrow a$	$\sigma \rightarrow \pi^*$
$n$		$n \rightarrow \sigma^*$	$n \rightarrow a$	$n \rightarrow \pi^*$
$\pi$		$\pi \rightarrow \sigma^*$	$\pi \rightarrow a$	$\pi \rightarrow \pi^*$

# Substitution Mechanisms Require New Elementary Steps: Nucleophile Association [A<sub>N</sub>]

$\ddot{\text{Nu}}^-$  is the nucleophile

[A<sub>N</sub>] involves an  $n \rightarrow a$   
 $\sigma$ -type interaction

## Curved Arrows Imply the Frontier Orbitals

Curved arrows indicate the HOMO-LUMO pair (Frontier Orbitals) involved in an elementary step. The tail of the arrow implies the filled orbital (HOMO) is non-bonded electron pair,  $n$ . The head of the arrow points to an empty orbital on the carbocation, suggesting that an atom-centered empty orbital (LUMO,  $a$ ) accepts the electron pair. **A good nucleophile will have a high energy  $n$ .**

empty filled	$\sigma^*$	$a$	$\pi^*$
$\sigma$	$\sigma \rightarrow \sigma^*$	$\sigma \rightarrow a$	$\sigma \rightarrow \pi^*$
$n$	$n \rightarrow \sigma^*$	$n \rightarrow a$	$n \rightarrow \pi^*$
$\pi$	$\pi \rightarrow \sigma^*$	$\pi \rightarrow a$	$\pi \rightarrow \pi^*$
